

Open a market, not just a token.

One transaction opens a bonding-curve market that trades immediately — with its own terminal, an agent, and a price any machine can pay from another chain.

A launchpad hands you a token page. We hand you a venue.

Four things arrive with the launch transaction. No listing step, no application, no word from us.

- **A trading terminal**

Candles from one second to one year, RSI, MACD, Bollinger, VWAP, a live order book and a trade feed — built for a market that is minutes old.

- **An agent that answers for it**

Ask it about the curve, the fee split, the depth. It carries its own token and curve addresses, and inference runs on **0G Compute**.

- **A cross-chain price**

A buyer holding only USDC on Base takes a position without bridging and without ever holding the market's gas token. Paid over plain HTTP.

- **Buyers that are machines**

An MCP server exposes every market to AI agents — discover, quote, buy, read history. A new market answers on the first request.

Shipped since the last check-in

MCP server

Six tools live at </api/mcp> — an AI agent can list markets, quote one, pay for it and read its full history. Streamable HTTP, no auth, no API key. The payment path is not reimplemented: the 402 an agent receives is the gateway's own challenge, passed through.

x402 settled

Cross-chain buys now settle with **real funds** — USDC paid on Base, tokens delivered by the curve on the destination chain, buyer never holds its gas token. Delivery runs before the charge, so a failed fill costs us and not the buyer.

Own indexer

Envio HyperIndex on Monad: full history from the factory's deploy block, **1.93M blocks in under 45 seconds**, checked figure by figure against what the curve contracts store. Read-only GraphQL is public and anonymous.

Trading terminal

Nine timeframes from 1s to 1y with a full indicator set, live order book and trade feed — the piece that makes a minutes-old market actually tradable rather than just listed.

Four layers of OG, all in production

Not "deployed on OG". Every launch touches three OG services, and one of them from a market that trades on another chain.

● OG Compute — the market agents

Every market's agent runs on the OG router (`glm-5.3`), and launch artwork is generated there too. **Each market is a permanent inference consumer**, not a one-off call.

● OG DA — launch metadata anchored

All three live markets have a real storage transaction on OG. **Including the market that trades on Monad** — its metadata is anchored to OG, so OG carries provenance for markets it does not host.

● OG Mainnet — factory + markets

Curve factory `0.11.0` live. Two of three markets are on OG; the largest has **21 swaps** and has burned **7.11** tokens through permissionless buybacks.

● TDX attestation — read, not claimed

The router reports TDX via dstack for all three models we call, and `/api/tee` serves that declaration raw. We state that we read it and do not verify the quote ourselves.

ERC-8004 identity registry is present on OG and binding is verified against `owner0f` at launch. It records an identity — it does not start a strategy, and we do not claim otherwise.

What is real, and what is missing

3

live markets, two of them on 0G

34

swaps on-chain, verified against contract storage

4

mainnets with the factory live

0

markets opened by someone other than us

- **The gap, stated plainly**

Every market so far shares one creator wallet — visible to anyone who opens the explorer, so there is no point framing it otherwise. The engine works end to end; distribution has not started. That is exactly what we came to Founder House to fix.

- **What we changed first**

We stopped selling "launch a token". The site now leads with the venue, and we removed every claim we could not verify in code — including a planned-integration card and four tool descriptions that existed nowhere in the repository.

WHY CREDITS GO FURTHEST HERE

0G is the cheapest place in our stack to onboard a creator

There is no launch fee — the factory function is not payable , so one cannot be added later. A creator pays gas and nothing else, measured against the deployed factory:

CHAIN	COST TO OPEN A MARKET	VS 0G
0G Mainnet	\$0.0024	—
Monad Mainnet	\$0.0071	3×
Base Mainnet	\$0.0459	19×
Arbitrum One	\$0.1539	64×

● What this means for a campaign

The same credit budget onboards roughly **19× more creators on 0G than on Base**, and 64× more than on Arbitrum. And every funded launch leaves 0G with a new contract pair, a DA write, and an agent that keeps consuming 0G Compute for as long as the market lives.

Measured 15 September 2026, and read live on the site rather than written by hand — gas price and native price both move, so any figure typed into a slide is a snapshot.

Two campaigns, both settled on-chain

- **Credit Campaign — "Open your market on 0G, free"**

0G credits cover the launch gas and a starter buyback, so a creator with an audience but no crypto can open a real market.

Anti-farm: one funded launch per wallet, and the credit is released only after the market records swaps from several distinct addresses. A dead market earns nothing, so the budget follows real activity rather than sign-ups.

- **Galxe Campaign — five quests, every one verifiable**

No screenshots and no self-reporting. Each quest maps to an event a verifier can read off 0G:

Open a market · trade one · **trigger a buyback** — permissionless, and it burns supply · buy a market from another chain over x402 · bind an ERC-8004 identity you own.

The buyback quest is the one we would push hardest: anyone may call it, no key gates it, the funds cannot leave the contract, and every call permanently reduces supply. Engagement that costs the treasury nothing and leaves a burn on 0G behind it.

Three, and all three are measurable

First outside creators

Ten markets opened on 0G by people who are not us. This is the only number that changes what we are — everything else is already built and waiting.

A machine buy, reproduced

A third party connects their own agent to our MCP endpoint and buys a market without a human in the loop. Not a video — a flow anyone in this room can run themselves.

Agents that act, on 0G Compute

Today a market's agent answers questions. The next step is scheduled action on 0G Compute — buyback timing and depth reporting — which turns every market into a recurring 0G workload instead of a chat window.

Everything on these slides can be checked without us: markets and swaps at adexto.xyz/explorer, the agent tools at adexto.xyz/mcp, contract addresses and honest status at adexto.xyz/docs.
